

Corporate Debt Restructuring, Bank Competition and Stability: Evidence from India

Mostak Ahamed and Sushanta Mallick

Queen Mary, University of London, UK

December 2015

Outline

- 1 Introduction**
 - Corporate debt restructuring Programme
 - Bank competition and stability
- 2 Data and Methodology**
- 3 Empirical Results**
 - Competition-fragility relationship
 - The impact of CDR on bank stability
 - Empirical results: DID and selection bias
- 4 Summary**

Bankruptcy in India

No unified bankruptcy code in India

- On average, it takes 4.3 years (World Bank).
- Twice as in **China**
- Banks can only recover **25.7 cents/Dollar**.
- Kingfisher grounded in 2012 with debts of \$1.5 billion.

What is Corporate Debt Restructuring (CDR) Programme?

CDR

- CDR is an efficient **out-of-court** institutional mechanism for banks/FIs to restructure corporate debts of Rs.100 million and above in **multiple-banking accounts**.
- It is **three-tiered** mechanism with a standing forum, empowered group and the CDR cell.

Regulatory forbearance on asset classification and provisioning

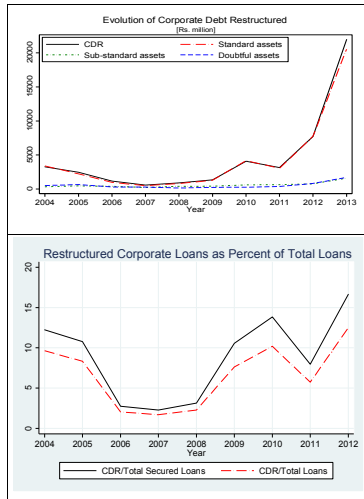

- Banks were allowed to make **concessional provision** of 2% on any restructured standard assets (Working Group, 2012).
- CDR is a conduit for bankers **to hide NPLs to hike profitability**.

▶ More on CDR

Evolution of restructured corporate debt

The taming of the restructuring

- On November 2012, RBI raised provision on restructured loans to 2.75% from just 2% previously.
- Provision on any **new restructured standard loan** is 5% from June 1, 2013.

Bank competition-stability relationship

Market power-stability hypothesis

- **More** concentrated and **less** competitive banking systems are **more stable** (Keeley, 1990; Casu, Girardone and Molyneux, 2012; Liu, Molyneux and Wilson, 2013; Fu, Lin and Molyneux, 2014)
- More profits provide a **buffer** against fragility and provide incentives against **excessive risk** taking.

Competition-stability hypothesis

- Greater competition contributes to sustain stability in the banking market (Boyd and De Nicolo, 2005)
- Higher market power of banks increases the **borrowing cost of entrepreneurs**, who eventually likely to default on their loan.

The existing studies on Indian banking sector

Bank ownership and efficiency studies

- **Given** the heterogeneous bank sizes and mixed ownership groups, **most** of the Indian studies explored **either** the link between ownership structure and performances (e.g., Sarkar et al., 1998; Bhaumik and Dimova, 2004) **or** the bank efficiency gap among the public, private and foreign banks (e.g., Das and Kumbhakar, 2012; Casu, Ferrari and Zhao, 2013)

Legal reforms and institutional mechanism to curtail credit risk

- Taking the **Debt Recovery Tribunals Act of 1993**, Visaria (2009) shows that the establishment of these tribunals led to a significant reduction in both delinquency rates and the cost of loans.
- Following a securitization reform in India, that is, the **SARFAESI Act of 2002**, Vig (2013) shows that **strengthening of creditor rights** led to a reduction in secured debt, total debt, debt maturity, and asset growth, and an increase in liquidity hoarding by firms.

Measuring bank risk

Following Turk-Ariss (2010), we used assets returns, its volatility and leverage to calculate Z-Score:

$$Z - score_{it} = \frac{ROA_{it} + EQA_{it}}{\sigma_{it}^{ROA}}$$

- where ROA is the return on assets, EQA is the equity over assets and σ_{it}^{ROA} is the standard deviation of ROA .
- For example: Average $Z - Score$ of 3.3 means that ROA has to drop by **3.3 times** of its Standard deviation to deplete bank equity.

The Evolution of bank stability

Note: Figure A1. **Evolution of banking stability.** Following Vig (2013), de-meaning of Z-score is done for each groups (Member and Non-Member), and then we plot the time series of de-meaned values of Z-score. It clearly shows before entering into CDR, member banks had a declining trend from the year 2001 to 2003. From 2004 to 2012, stability of the member banks increased as compared to non-member banks given CDR fully operationalized in the year 2004.

Treatment and control group's before-after kernel density plot

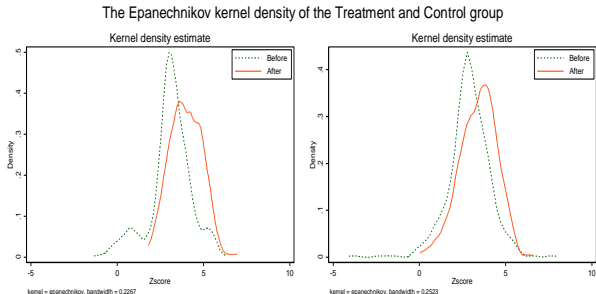

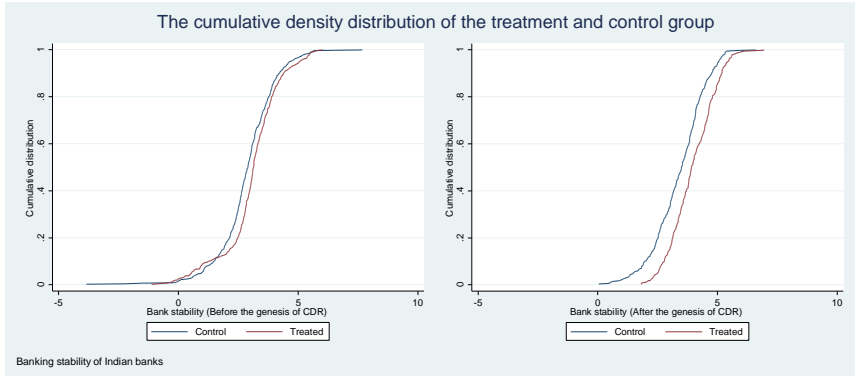

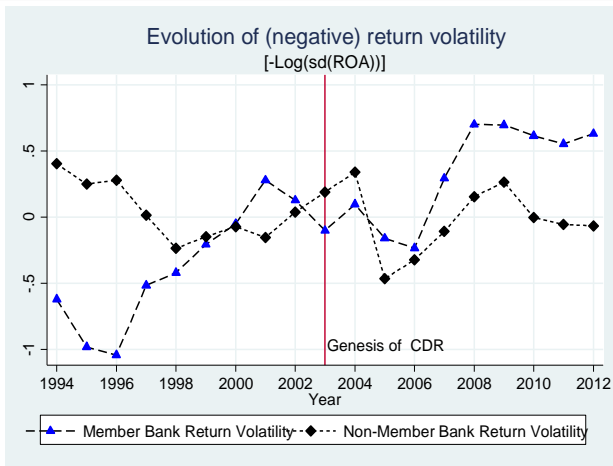

Figure A2: Kernel density of Indian banking stability

Note: Figure A2. **Kernel density of Indian banking stability (Zscore)**. This figure depicts the Epanechnikov kernel density of the logarithm of Z-score for both the member banks (“treatment”) group and non-member banks (“control”) group. It shows that *stability of the treated group has increased more (left graph) compared to control groups (right graph)*.

Cumulative density distribution plots

The Evolution of bank (negative) return volatility

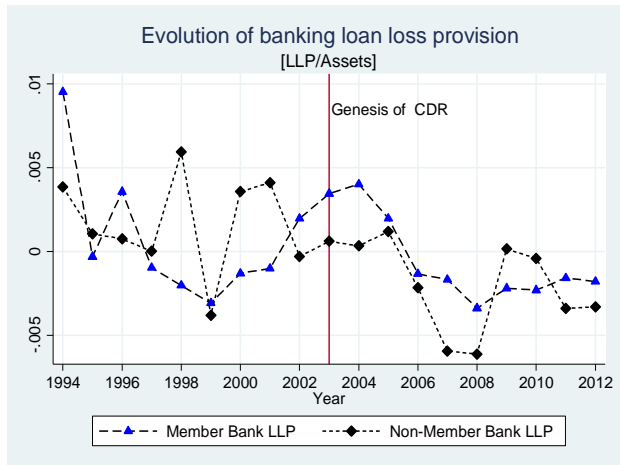

Note: Figure A3. **Evolution of banking (negative) return volatility.** Following Vig (2013), de-meaning of return volatility is done for each groups (Member and Non-Member), and then we plot the time series of de-meaned values of return volatility. Following Beck et al., (2013), we have transformed (logarithm) return volatility to make it proportional to bank stability.

The Evolution of non-performing loans

Note: Figure A4. **Evolution of non-performing loans.** Following Vig (2013), de-meaning of non-performing loan ratio is done for each groups (Member and Non-Member), and then we plot the time series of de-meaned values of non-performing loan. It clearly shows that before entering into CDR, member banks had higher non-performing loans, which was decreased in the treatment period. NPL is rising again may be because 20-25% of the restructured loans are assumed to be bad gradually.

The Evolution of loan loss provisions

Note: Figure A5. **Evolution of loan loss provisions.** Following Vig (2013), de-meaning of loan loss provision is done for each groups (Member and Non-Member), and then we plot the time series of de-meaned values of non-performing loan. It clearly shows that before entering into CDR, member banks had higher loan loss provision, which is decreased in the treatment period may be due to regulatory forbearance on asset classification and provisioning.

Measuring market power

Following Berger et al. (2009) and Koetter et al. (2012), we calculated market power at the bank-level as:

$$Lerner_{it} = \frac{P_{it} - MC_{it}}{P_{it}}$$

- where P is the ratio of total revenue to assets, MC is the **marginal cost** of producing an additional unit of output.
- MC is estimated using **stochastic frontier analysis (SFA)** where we employed **three inputs** (i.e. labour, capital and borrowed funds) and **two outputs** (i.e. loans and securities).

Stochastic frontier analysis (SFA)

$$\begin{aligned} \ln TOC_{it} = & \beta_0 + \sum_{j=1}^3 \beta_j \ln W_{j,it} + \sum_{p=1}^2 \gamma_p \ln Y_{p,it} + \delta \ln(Z_{it}) + \sum_{j=1}^3 \left(\frac{S_j}{2}\right) (\ln W_{j,it})^2 + \sum_j^3 \sum_k^3 \eta_{jk} \ln W_{j,it} \ln W_{k,it} \\ & + \sum_{p=1}^2 \left(\frac{\theta_p}{2}\right) (\ln Y_{p,it})^2 + \left(\frac{\kappa_{12}}{2}\right) \ln Y_{1,it} \ln Y_{2,it} + \sum_{j=1}^3 \sum_{p=1}^2 \lambda_{jp} \ln W_{j,it} \ln Y_{p,it} + \sum_{k=1}^2 \rho_k \text{trend}^k + \sum_{j=1}^3 \varepsilon_j \ln W_{j,it} \text{trend} \\ & + \sum_{p=1}^2 \omega_p \ln Y_{p,it} \text{trend} + \varepsilon_{it} \end{aligned}$$

- where *TOC* is the total costs including financial and operating cost.
- To estimate *MC* we take **first derivative** with respect to outputs.

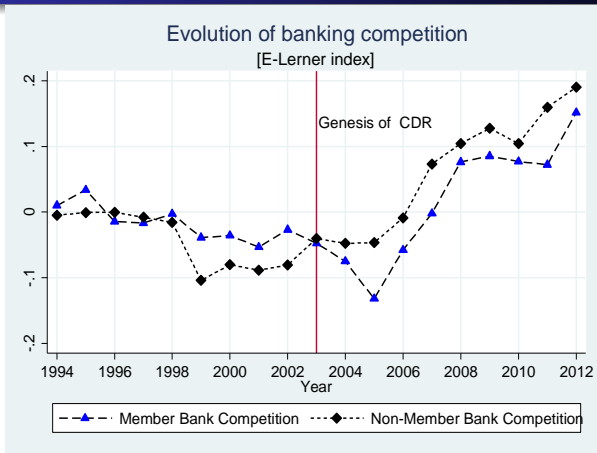

$$\begin{aligned} MC_{it} = & \frac{TOC_{it}}{Y_{1,it}} \left[\gamma_1 + \theta_1 \ln Y_{1,it} + \left(\frac{\kappa_{12}}{2}\right) \ln Y_{2,it} + \sum_{j=1}^3 \lambda_{1j} \ln W_{j,it} + \omega_1 \text{trend} \right] \\ & + \frac{TOC_{it}}{Y_{2,it}} \left[\gamma_2 + \theta_2 \ln Y_{2,it} + \left(\frac{\kappa_{12}}{2}\right) \ln Y_{1,it} + \sum_{j=1}^3 \lambda_{2j} \ln W_{j,it} + \omega_2 \text{trend} \right] \end{aligned}$$

Scatterplot: Lerner vs. Marginal cost

Note: Scatterplot of Lerner indices and marginal cost

The Evolution of bank competition (Efficiency-adjusted Lerner indices)

Note: Figure A6. **Evolution of bank competition.** Following Vig (2013), de-meaning of efficiency-adjusted Lerner indices is done for each groups (Member and Non-Member), and then we plot the time series of de-meaned values of Lerner indices. It clearly shows that during treatment period, member banks could increase market power substantially may be because member banks could exploit CDR mechanism to “hide NPLs and hike profitability”, enhancing margins and subsequently market power.

The impact of bank competition on stability:

We used an instrumental variable technique with a GMM estimator to circumvent potential **endogeneity** issue. It is the **heteroskedasticity and autocorrelation consistent (HAC)** variance estimation of Newey and West (1987):

$$\begin{aligned}
 \text{Bank risk}_{it} = & \alpha_i + \alpha_t + \beta_1 \text{Lerner}_{it} + \beta_2 \text{rreg}_t \\
 & + \sum \gamma \cdot (\text{Bank Controls})_{it} + \sum \delta \cdot (\text{Macro})_{it} + \varepsilon_{it} \quad (1)
 \end{aligned}$$

- *Bank risk* are **either Z-Score or logarithm transformation of negative standard deviation of ROA.** ▶ Measuring bank risk
- *Lerner* are **either conventional or efficiency-adjusted Lerner indices.** ▶ Measuring market power
- *rreg* is **deregulation dummy.** ▶ Control variables

Our dataset comprises of an unbalanced panel of up to **110 commercial banks from 1992-2012**. We draw data from a number of sources:

- The bank level dataset is compiled from the **Reserve Bank of India**.
- The macro data is compiled from the World Bank **World Development Indicators (WDI)**.
- IV instruments are taken from **the Heritage Foundation**.
- We deflate all monetary values to 1994 (1993-94 = 100) prices using the wholesale price index (WPI). [▶ Summary statistics](#)

Control variables

| Variables | Notation | Definitions | Source |
|--------------------------------|-------------------|--|--------|
| <i>Frontier Arguments</i> | | | |
| Costs of funds | W_1 | Sum of interest expenses on deposits, interest expenses on RBI and inter-bank funds divided by sum of deposits and borrowings from RBI and others | RBI |
| Cost of labour | W_2 | Payments to and provisions for employees divided by total assets | RBI |
| Cost of capital | W_3 | Other operating expenses divided by fixed assets | RBI |
| Total loans | Y_1 | Total loans and advances | RBI |
| Other earning assets | Y_2 | Total investments | RBI |
| Equity | z | Sum of capital and reserves and surplus | RBI |
| Operating costs | <i>TOC</i> | Sum of Interest Expenses and Operating Expenses | RBI |
| Profit before tax | <i>PBT</i> | Operating income less TOC | RBI |
| Negative profit indicator | <i>NPI</i> | Takes 1 for the negative profit or else 0 | Own |
| <i>Bank risk measures</i> | | | |
| Z-score | <i>Z - score</i> | Sum of return-on-assets (ROA), defined as net profit over assets, and equity ratio (EQA), defined as equity over assets, divided by standard deviation of (ROA) of each bank over past three years (calculated using a rolling window) | Own |
| Return Volatility | σ_{ROA} | Standard deviation of ROA for each bank, calculated over past 3 years | Own |
| Credit risk | <i>NPL</i> | Non-performing loans divided by total loans | RBI |
| <i>Market Power</i> | | | |
| C-Lerner | <i>C - Lerner</i> | A bank-level non-structural indicator of bank competition, measured by using fixed-effects method, with lower values indicating higher competition in the banking sector | Own |
| E-Lerner | <i>E - Lerner</i> | A bank-level non-structural indicator of bank competition, an efficiency-adjusted Lerner index, measured by using a stochastic frontier analysis approach, with lower values indicating higher competition in the banking sector | Own |
| <i>Bank characteristics</i> | | | |
| Bank Size | <i>size</i> | Logarithm of total assets | RBI |
| Loan ratio | | Total performing loans divided by total assets | RBI |
| Provision ratio | <i>LLP</i> | Total loan loss provision divided by total assets | RBI |
| Net interest margin | <i>NIM</i> | Net interest income to total earning assets | RBI |
| Income diversification | <i>DIV</i> | Non-interest income divided by total operating income | RBI |
| Equity ratio | <i>EQA</i> | Total equity divided by total assets | RBI |
| <i>IV Instruments</i> | | | |
| Merger | <i>merger</i> | Takes value equal to one for the year and thereafter if a bank enters into mergers and acquisitions activity or else zero | Own |
| Business Freedom | <i>bfree</i> | The business freedom is taken from Heritage Foundation, it is a number between 0 and 100, with 100 equaling the freest business environment | HF |
| <i>Macroeconomic variables</i> | | | |
| GDP per capita | <i>gdppc</i> | Logarithm of GDP per capita | WDI |
| Volatility of GDP | $\sigma_{5,gdp}$ | Standard Deviation of real GDP growth rate calculated over past five years using a rolling window | WDI |
| Inflation | <i>inf</i> | Annual growth rate of consumer price index | WDI |

The effect of CDR on bank stability:

Following Bertrand and Mullainathan (2003), we examine the effect of CDR on bank risk-taking by using a **difference-in-difference (DID)** approach as follows:

$$\begin{aligned} \text{Bank risk}_{it} = & \alpha_i + \alpha_t + \beta_1 \cdot \text{CDR}_{i,t-1} + \beta_2 \text{Lerner}_{i,t-1} \\ & + \sum \gamma \cdot (\text{Bank Controls})_{it} + \sum \delta \cdot (\text{Macro})_{it} + \varepsilon_{it} \quad (2) \end{aligned}$$

- where, *CDR* is an indicator variable that takes a value equal to one if a bank signed **inter-creditor agreement (ICA)** and became a member of CDR programme in 2003 and thereafter or else zero.
- **the coefficient β_1 captures the DID effect** i.e., the treatment effects of CDR on financial stability.

The interactive effect of CDR with bank competition

We use following difference-in-difference-in-differences (DDD) approach (Long et al. 2010; Vig, 2013) to investigate interaction effect of CDR and bank competition on stability:

$$\begin{aligned} \text{Bank risk}_{it} = & \alpha_i + \alpha_t + \beta_1 \cdot (\text{CDR})_{i,t-1} + \beta_2 \text{Lerner}_{i,t-1} \\ & + \beta_3 \cdot \text{CDR}_{i,t-1} \times \text{Lerner}_{i,t-1} \\ & + \sum \gamma \cdot (\text{Bank Controls})_{it} + \sum \delta \cdot (\text{Macro})_{it} + \varepsilon_{it} \end{aligned} \quad (3)$$

- where the coefficient β_3 captures the DDD effect.

Basic empirical strategy: difference-in-differences (DID)

Table 4a: This table provides basic empirical strategy.

Member banks are those who participated and Non-member banks are those who did not participate in the CDR programme. 'Before' refers to 1992-2003 and 'After' refers to period from 2004 to 2012. DD refers to Difference-in-Differences. Diff is interpreted as the percentage change from period before to after. DD is the percentage change in the member banks compared to non-member banks. ***, **, and * indicate statistical significance at the 1%, 5% and 10% respectively.

| Outcome variable | Before | | | After | | | DD |
|-------------------|------------|--------|----------|------------|--------|----------|-----------------|
| | Non-Member | Member | Diff | Non-Member | Member | Diff | |
| Z-Score | 2.881 | 3.079 | 0.197*** | 3.407 | 3.973 | 0.566*** | 0.369*** |
| Std. Error | 0.051 | 0.057 | 0.076 | 0.059 | 0.058 | 0.083 | 0.113 |
| Return volatility | 5.218 | 5.984 | 0.766*** | 5.156 | 6.671 | 1.516*** | 0.75*** |

Sensitivity analysis: Matching estimators

Table 6: Sensitivity analysis of the impact of CDR using matching techniques

| VARIABLES | Z-score $[(ROA+EQA)/(sd(ROA))]$ | | | Return volatility $[-\log(sd(ROA))]$ | | |
|--------------------------|---------------------------------|---------------------|-------------------|--------------------------------------|---------------------|-------------------|
| | Kernel matching | Stratified Matching | Abadie and Imbens | Kernel matching | Stratified Matching | Abadie and Imbens |
| ATT | 0.58*** | 0.48*** | 0.84*** | 0.57*** | 0.45*** | 0.70*** |
| SE | [0.08] | [0.09] | [0.13] | [0.09] | [0.09] | [0.13] |
| <i>t</i> -statistics | 7.04 | 5.13 | 6.59 | 6.18 | 4.94 | 5.19 |
| Observations | 1,403 | 1,403 | 1,240 | 1,403 | 1,403 | 1,241 |
| Common support condition | √ | √ | √ | √ | √ | √ |

Note: Three matching methods are used include Kernel matching, Stratified matching and the nearest-neighbour bias-corrected matching estimators proposed by Abadie and Imbens (2006). Abadie and Imbens method adjusts the differences within the matches for the differences in covariate values. Following Abadie et al. (2004), we use four matches per observation. The variables that are used for the matching (or bias-adjusted variables) include the age of the bank, listed bank dummy (equal to one if a bank is listed in the stock market, or else zero), the number of employee, the number of branches and the logarithm of total assets. ATT is the average treatment effect for the treated. The standard errors in Abadie and Imbens are heteroskedasticity-consistent, and Z-stats are reported. For the rest, we report absolute values of bootstrapped *t*-stats in bracket. Observation size is reduced as we do not have information on the number of employee for all banks prior to 1997. The number of observation also differs due to the difference in the underlying matching approaches. We run balancing test on all the independent variables included in the logit regression, which has been satisfied. Hosmer–Lemeshow test confirmed goodness-of-fit of logit model (unreported but available upon request).

Logit model, descriptive statistics and distribution of matched sample

Table A3: Propensity to participate into CDR- Logit model and descriptive statistics

| Panel A: Logit model | | | Panel B: Descriptive statistics of matched sample | | | |
|------------------------------|-------------|---------|---|------------------|---------|---------|
| Dependent variable: CDR | Coefficient | S.E. | Member banks | Non-member banks | p-value | t-stats |
| Log of Age | 0.887*** | [0.343] | 4.23 | 4.16 | 0.28 | 1.08 |
| Log of number of employee | -2.434*** | [0.713] | 9.18 | 9.28 | 0.50 | -0.67 |
| Log of number of branches | 1.272** | [0.519] | 6.54 | 6.65 | 0.42 | -0.80 |
| Listed bank dummy | 1.879* | [0.963] | 0.89 | 0.92 | 0.35 | -0.94 |
| Bank size (log total assets) | 2.265*** | [0.368] | 12.10 | 12.15 | 0.65 | -0.46 |
| Observation | 1,340 | | | | | |

Note: In Panel A, the dependent variable CDR is an indicator variable that takes value 1 for banks which participate into Corporate Debt Restructuring Mechanism in 2003 and thereafter or else zero. We use the logarithm of total age of individual banks, the number of employees, branches, listed dummy and banks size of each banks in the Logit model in order to measure the propensity score where standard errors are clustered at the bank level and reported on brackets. Since information on bank employees are missing prior to 1997, our total number of observations is reduced to 1340. The Hosmer–Lemeshow test (p-value = 0.62) confirms the goodness-of fit of Logit model. In Panel B, we shows the descriptive statistics of the matched sample for which p-values are reported.

Figure A2: Graph on the left shows how several blocks where member and non-member banks were matched. Graphs on the right shows the Kernel distribution of the matched and unmatched banks.

Summary

- **Greater pricing power** is positively associated with **banking stability**.
- After second phase of deregulation, stability of Indian banking sector improved substantially.
- **The CDR programme** mitigated *debt overhang* of corporates and *NPLs overhang* of banks.
- The **difference-in-difference approach** shows that **member banks** of CDR system experience a **significant improvement** in banking stability.
- However, the **positive effect of CDR** on banking stability **diminishes** for the member banks at the **higher market power level**.

Policy implications

- To **ensure no scope for ever-greening** (Peek and Rosengren, 2005), the RBI should tighten the macro-prudential norms and emphasise on **international best practice in asset classification and provisioning of restructured corporate loans**.
- Member banks should increase provisioning on existing restructured loans gradually; otherwise **any substantial loss might lead them to exhaust capital base at a point where insolvency or illiquidity would be inevitable**.

Thank You

Thank You!

Measuring bank risk

Following Turk-Ariss (2010), we used assets returns, its volatility and leverage to calculate Z-Score:

$$Z - score_{it} = \frac{ROA_{it} + EQA_{it}}{\sigma_{it}^{ROA}}$$

- where ROA is the return on assets, EQA is the equity over assets and σ_{it}^{ROA} is the standard deviation of ROA .
- For example: Average $Z - Score$ of 3.3 means that ROA has to drop by **3.3 times** of its Standard deviation to deplete bank equity.

[Return](#)

Measuring market power

Following Berger et al. (2009) and Koetter et al. (2012), we calculated market power at the bank-level as:

$$Lerner_{it} = \frac{P_{it} - MC_{it}}{P_{it}}$$

- where P is the ratio of total revenue to assets, MC is the **marginal cost** of producing an additional unit of output.
- MC is estimated using **stochastic frontier analysis (SFA)** where we employed **three inputs** (i.e. labour, capital and borrowed funds) and **two outputs** (i.e. loans and securities).

[Return](#)

Stochastic frontier analysis (SFA)

$$\begin{aligned}
 \ln TOC_{it} = & \beta_0 + \sum_{j=1}^3 \beta_j \ln W_{j,it} + \sum_{p=1}^2 \gamma_p \ln Y_{p,it} + \delta \ln(Z_{it}) + \sum_{j=1}^3 \left(\frac{S_j}{2}\right) (\ln W_{j,it})^2 + \sum_j^3 \sum_k^3 \eta_{jk} \ln W_{j,it} \ln W_{k,it} \\
 & + \sum_{p=1}^2 \left(\frac{\theta_p}{2}\right) (\ln Y_{p,it})^2 + \left(\frac{\kappa_{12}}{2}\right) \ln Y_{1,it} \ln Y_{2,it} + \sum_{j=1}^3 \sum_{p=1}^2 \lambda_{jp} \ln W_{j,it} \ln Y_{p,it} + \sum_{k=1}^2 \rho_k \text{trend}^k + \sum_{j=1}^3 \varepsilon_j \ln W_{j,it} \text{trend} \\
 & + \sum_{p=1}^2 \omega_p \ln Y_{p,it} \text{trend} + \varepsilon_{it}
 \end{aligned}$$

- where *TOC* is the total costs including financial and operating cost.
- To estimate *MC* we take **first derivative** with respect to outputs.

$$\begin{aligned}
 MC_{it} = & \frac{TOC_{it}}{Y_{1,it}} \left[\gamma_1 + \theta_1 \ln Y_{1,it} + \left(\frac{\kappa_{12}}{2}\right) \ln Y_{2,it} + \sum_{j=1}^3 \lambda_{1j} \ln W_{j,it} + \omega_1 \text{trend} \right] \\
 & + \frac{TOC_{it}}{Y_{2,it}} \left[\gamma_2 + \theta_2 \ln Y_{2,it} + \left(\frac{\kappa_{12}}{2}\right) \ln Y_{1,it} + \sum_{j=1}^3 \lambda_{2j} \ln W_{j,it} + \omega_2 \text{trend} \right]
 \end{aligned}$$
